Basics of Cryptography

Confidentiality with Symmetric Encryption

Message Authentication and Hash Functions

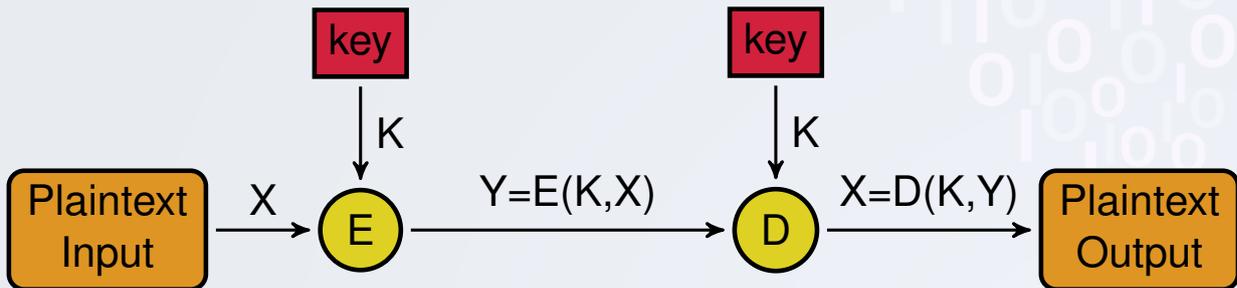

Public-Key Cryptography

Digital Signatures and Key Management

Practical Application: SSL/TLS

# What can cryptography do?

- Confidentiality ✓
- Integrity ✓
- Availability ✗
- Authenticity ✓
- Accountability ✓

# Caesar Cypher

- Named after Julius Caesar, although used long before.
- Representative of the substitution cypher algorithms.
- The encryption process shifts each letter a number of places. (key)
- Easily attackable by brute force.

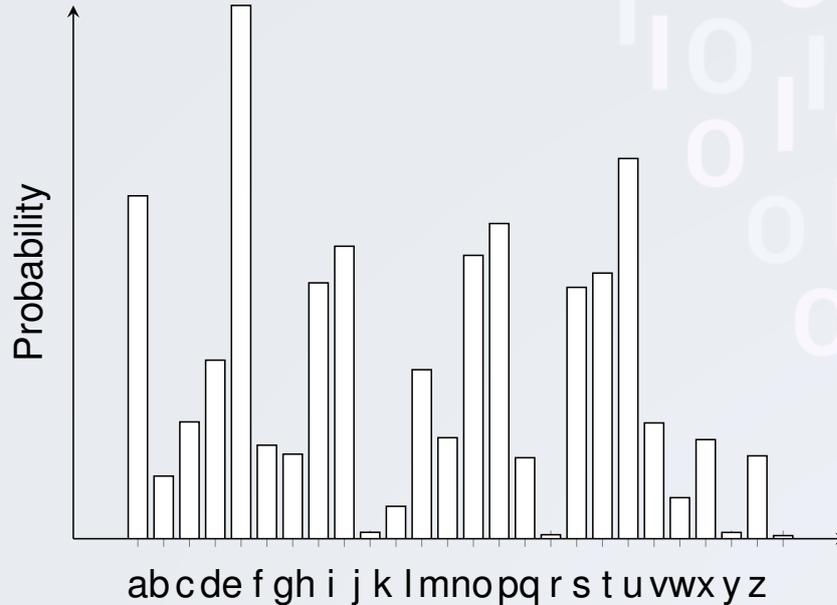

# Substitution Cypher

- The key is a substitution table.
- The encryption changes each letter by the corresponding in the table.
- Infeasible to break by brute force.
- Breakable by cryptanalysis.

# Substitution Cypher

- Working examples of old cyphers

[http://simonsingh.net/The\\_Black\\_Chamber/chamberguide.html](http://simonsingh.net/The_Black_Chamber/chamberguide.html)

# Vernam cipher

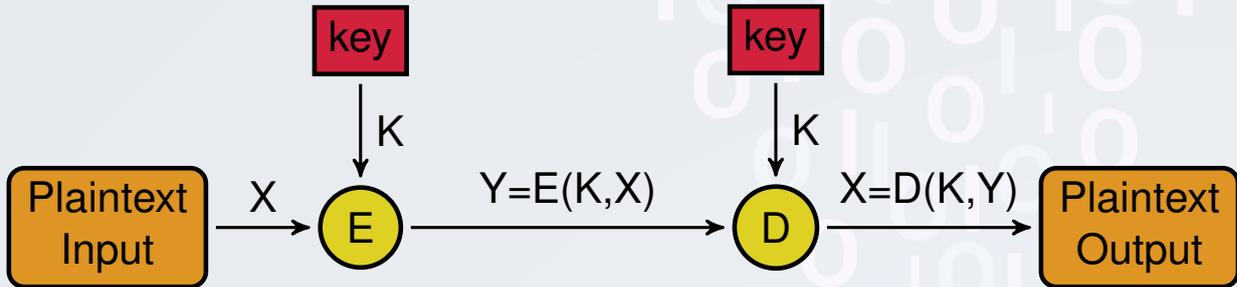

- Commonly known as One-time-pad.
- Proven to be unbreakable (Go Shannon!)
- Key must be as long as plain text and shared by peers.
- Key must be truly random and can be used only once.

# Randomness

- Cryptography relies heavily on random numbers.
- Quality of random numbers
  - Uniform distribution
  - Independence
- Pseudo-random numbers
  - Mathematical modular expression derives number from the last.
  - Good distribution and price, but bad independence.
- True-random numbers
  - Monitor random or chaotic physical process.
  - Good distribution and independence, but expensive.

# Symmetric Encryption

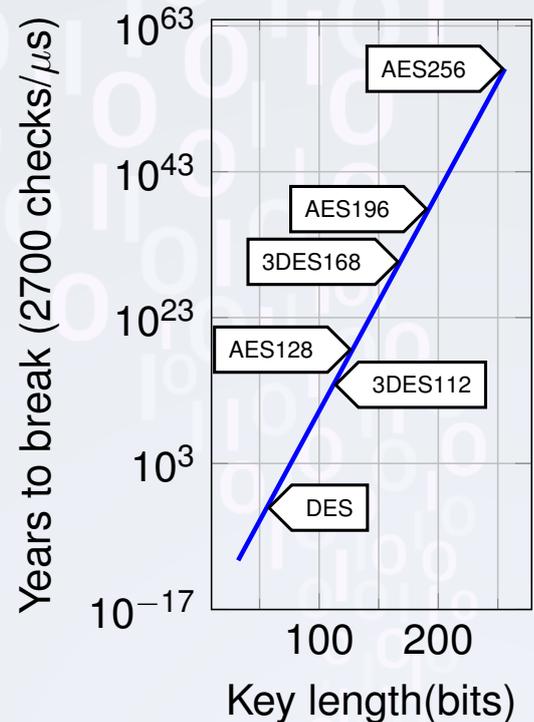

How robust is this?

- Strong encryption algorithm.
- **Cryptanalysis**: Mathematically derive  $X$  and/or  $K$  from  $Y$ . Or simplify brute-force.
- Keys subject to brute-force attacks
- Sender and receiver must obtain keys in secure fashion.

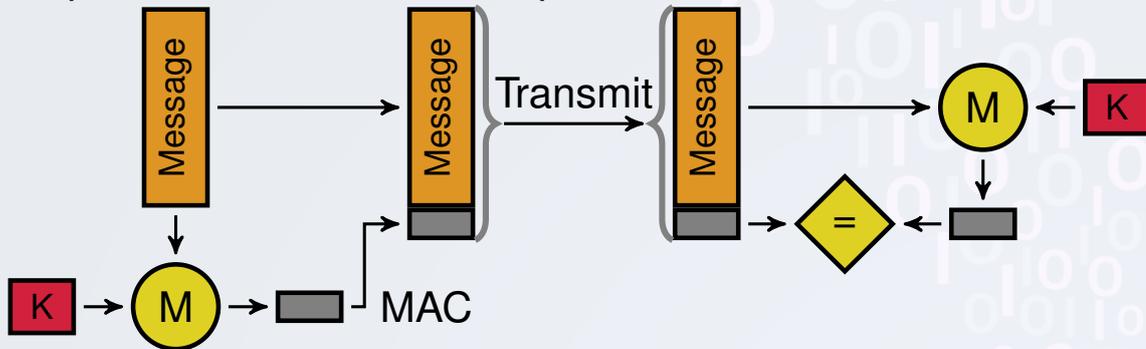

# Data Encryption Standard (DES)

- 64 bit blocks, 56 bit keys.  
Adopted NIST 1977
- Cryptanalysis not yet successful.
- 1997: call for replacement proposals.
- July 1998: \$250,000 machine cracks DES in 56h.
- Advanced Encryption Standard (AES) 128 bit blocks, 128,192,256 bit keys. Adopted 2001

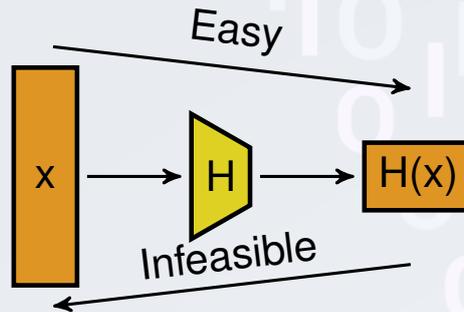

# Message Authentication with Symmetric Encryption

- No confidentiality.
- Protection against falsification, alteration, delay or replay.
- Message must contain metadata: error-detection code, sequence number, timestamp.

- Message Authentication Code (MAC)
- Last 16-32 bits of DES encrypted message.

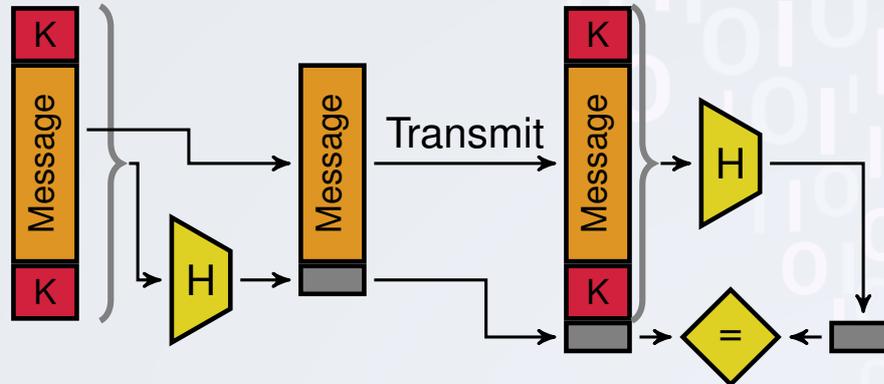

# One-way Hash Functions

- $x$ : “unlimited” size,  $H(x)$ : fixed length.
- Preimage resistant: guess  $x$  from  $H(x)$ .
- 2<sup>nd</sup> preimage resistant: find  $y \neq x$  such that  $H(x) = H(y)$ .
- Collision resistant: find any  $x$  and  $y$  such that  $H(x) = H(y)$ .
- Hash function crisis: RIPMED-160, SHA-256 and SHA-512.

# Message Authentication with One-way Hash Functions

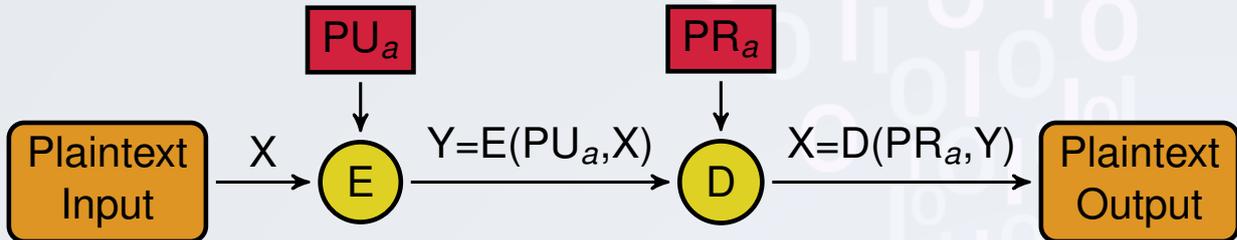

- One-way Hash Functions are faster than Symmetric Encryption
- Using shared secret value (K).

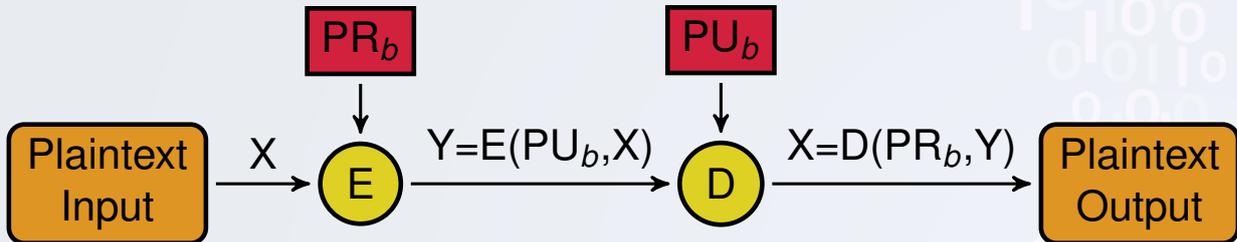

- Secure Hash Algorithm(SHA): SHA-1 160 bit long, used but weaker than expected. Currently 256, 384, 512 bit long.
- Use in password storage and intrusion detection.

# Public-Key Encryption

- Proposed by Diffie and Hellman in 1976.
- Keys are created in pairs. One reverses the other.
- Bob sends confidential message to Alice.

- Bob sends authentic message to Alice.

# Public-Key Cryptography

## ■ Myths:

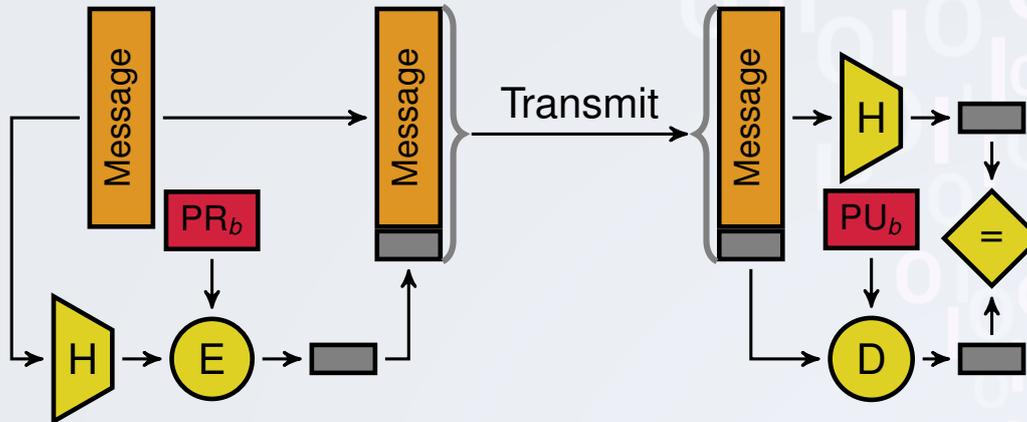

- Public-key encryption is more secure than Symmetric-key encryption.
- Public-key encryption makes symmetric obsolete.
- Public-key distribution is easier than Symmetric-key distributions.

## ■ Implementations:

- Rivest, Shamir and Adleman (RSA) Proposed in 1978.
- Digital Signature Algorithm (DSA) Proposed in 1991.  
Stronger than RSA. Faster signing, but slower verifying.
- Elliptic Curve Cryptography (ECC) Stronger than RSA.  
Allows shorter keys.

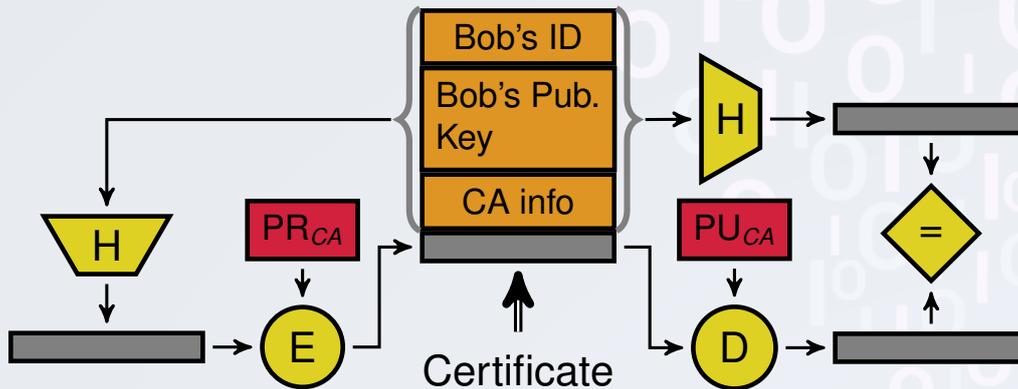

# Digital Signature

- Messages can be signed by encrypting MAC with private key.

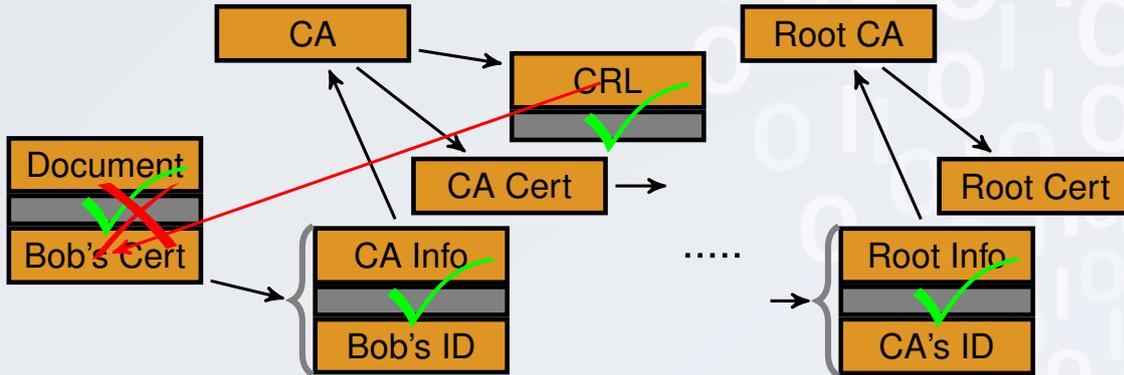

# Distribution of public keys

- **Certificate Authority** (CA) signs public keys (Certificate)

- Who certifies the CA? Chicken-and-egg problem.
- **Root CAs** distribute their public keys self-signed.
- Applications and OS ship with common root certificates.

# Certificate Chain of Trust

- Users can recursively validate signatures to the root CA.
- Certificate Revocation Lists(CRL) enumerate invalid certs.

# SSL/TLS Handshake
